

The impact of the RS–040 highway on wildlife roadkill patterns in Porto Alegre, Brazil

Gabrielle Zanettini Tres¹, Tiago Dominguez Pacheco¹, Vitor Gabriel Cardozo Silva¹, Paulo Guilherme Carniel Wagner², Walter Nisa-Castro-Neto³ and Cláudio Estêvão Farias Cruz^{1*}

ABSTRACT

Road infrastructure has severely affected the environment and wildlife. Understanding and mitigating these effects are essential conservation measures. This study aimed to evaluate fatal wildlife-vehicle collisions along an 80-km stretch of the Tapir Rocha highway (RS–040). Fieldwork was carried out between August 2015 and March 2019. Once a week, two observers were driven along the highway at an average speed of 40 km/h. All dead vertebrate sightings were investigated to document the species, carcass condition, and locations along the roadway. In total, 2,371 wild, domestic and unidentified dead animals were assessed and categorized into 137 species. The most affected classes were mammals ($n = 1,223$), and birds ($n = 704$). The most affected wild species were white-eared opossums (*Didelphis albiventris*, $n = 559$), black-and-white tegus (*Salvator merianae*, $n = 129$), and coypus (*Myocastor coypus*, $n = 102$). The carcass exposure assessments indicated that many ($n = 637$) animal deaths occurred the night before our arrival and that nocturnal species may also be more vulnerable to roads. Roadkill sightings peaked in the spring (34%) and summer (25%), probably due to reproductive activity and juvenile dispersal. Seasonal variations included a 50% reduction in reptile roadkill rates in autumn-winter compared to spring-summer, and a 20-percentage-point increase in the number of mammal road deaths in the winter. Thermally restricted reptile activity, and seasonal changes in carnivore food habits may explain these respective findings. Although most of the road deaths affected abundant and widely distributed species, a decrease in these populations may eventually become a conservation concern.

SIGNIFICANCE STATEMENT

This is an analytical study of wildlife roadkill along an 80-km stretch of highway (RS-040), in Porto Alegre, Rio Grande do Sul (RS), Brazil. We highlight the number of road deaths per species and their association with the seasons and the time of carcass exposure. Understanding the magnitude of these figures is essential for public awareness and the planning of wildlife management and conservation. Although they were not the focus of this study, incidents involving domestic animals were also documented.

INTRODUCTION

Land and maritime transport and infrastructure have caused a global biodiversity crisis (WWF 2022). Road expansion and vehicular traffic fragment habitats and affect the bioecology of wild animal species (Trombulak and Frissell 2000; Seiler 2001; Coffin 2007). In Brazil, an extensive highway network intersects biodiverse ecoregions where wildlife-vehicle collisions are one of the main causes of animal mortality, including endangered species (CBEE, 2022). While animal deaths and biodiversity loss are not the only repercussions (Trombulak and Frissell 2000; Coffin 2007), they may be the most frustrating ones (Clevenger *et al.* 2003; Taylor and Goldingay 2004; Bager and Rosa 2010; Abra *et al.* 2021). Worldwide estimates of annual wildlife mortality report thousands to millions of deaths (Van der Zande *et al.* 1980; Erickson *et al.* 2005; Forman and Alexander 1998). In Brazil, 475 million vertebrates are estimated to die on roads annually (Dornas *et al.* 2012; CBEE, 2022), mostly small and medium-sized vertebrates from the south and southeast (CBEE 2022). These numbers can negatively affect local wildlife populations (Ascensão *et al.* 2016), and highlight the need for education about the impact of roads and the importance of adequate infrastructure (Clevenger *et al.* 2001; Ascensão *et al.* 2013; Huijser *et al.* 2022). A comprehensive but succinct review of studies on wildlife-vehicle collisions in Brazil was recently published (Ferreira *et al.* 2023). Animal road deaths mainly occur due to (a) highways fragmenting habitats and interfering with the animal displacement ranges, especially along migration corridors, or (b) attraction to food on the roads (e.g., grains, seeds, fruits, plants, and dead animals) (Weiss and Vianna 2012; Costa and Dias 2013; Teixeira *et al.* 2013).

Species inventories and conservation status assessments measure declining wildlife populations or isolation, escalations in human-wildlife conflicts, and the effects of noise and other forms of pollution (Coffin 2007). These methods can also evaluate road characteristics and areas of environmental impact, such as road width, traffic speed and flow, proximity to protected areas, species occurrence and behavior, and population sizes (Godwin and Fahrig 2002; Rytwinski and Fahrig 2012 and 2013; Freitas *et al.* 2015). Monitoring wildlife roadkill involves an assessment of

local conservation efforts and the establishment of priority areas for conservation (Abra *et al.* 2021). However, the number of road deaths can be deceptively low because some injured animals go undetected (e.g., small animals), some retreat to hiding spaces to die (Baker *et al.* 2004), and others are removed by scavengers (Teixeira *et al.* 2013) or humans (Zaleski *et al.* 2009; Oliveira *et al.* 2023). Therefore, while animal deaths are common on Brazilian roads, records of wildlife-vehicle collisions and scientific reports may be imprecise or remain insufficient (Rosa and Mauhs 2004; Weiss and Viana 2012; Silva *et al.* 2013; Sássi *et al.* 2013; Ferreira *et al.* 2023). This study aimed to present the taxa of vertebrate roadkill, and evaluate associations between roadkill rates, seasonality, and hot spots along the RS-040 highway.

MATERIAL AND METHODS

Study area.

The Tapir Rocha Highway (RS-040) is located in the metropolitan mesoregion of Porto Alegre in Rio Grande do Sul (RS), and its total length is 94.85 km (Figure 1). It crosses two phyto-ecological regions as it runs from the boundary between Viamão and Porto Alegre all the way to Balneário Pinhal (IBGE 2014a). The vegetation up to highway kilometer #12 includes semi-deciduous seasonal forests and pioneer zones. Savanna vegetation originally dominated the higher regions of this undulating terrain, while the valleys and hillsides were covered by forested areas. Pioneer vegetation zones are most prominent along highway kilometer #44. The flat terrain was originally a mosaic of dry fields, marshes and sandbank scrubs. However, the vegetation has significantly changed along these stretches of highway. In the former segment, grasslands and forested areas have intruded, mainly due to agricultural practices. In the latter, rice crops are now common and the Brazilian peppertree (*Schinus terebinthifolius*), wild-coffee (*Casearia silvestris*), capororoca (*Myrsine umbellata*), and marica (*Mimosa bimucronata*) grow in the humid subtropical climate. The average annual precipitation is 1,450 mm, with no defined dry seasons. The average annual temperature is 17°C, with a mean of 22°C during the hot months. Highway RS-040 was chosen because of its location in Porto Alegre, the marked seasonal varia-

tions in traffic to the coast (EGR 2023), and certain environmental characteristics (e.g., ecosystems, migratory and endangered species, industry expansion, and agricultural production systems such as forestry, rice crops and livestock farming).

Sampling. Weekly fieldwork was scheduled between August 2015 and March 2019. Within this general routine, we acknowledge that the average interval between monitoring dates was 11 days. Two observers were driven along the highway RS-040 at an average speed of 40 km/h. Immediately after the junction with highway RS-118, the odometer was reset to zero as the car traveled west to east direction. The observers visually checked the right lane of the highway for roadkill. This leg of the trip ended at highway kilometer #92, near the entrance to Balneário Pinhal. The car would immediately turn around and drive east to west at the same speed, while the observers checked the left lane of the highway for roadkill. The taxa of the specimens we found were identified using previous reports (Achaval *et al.* 2007; Belton 2004; Deiques *et al.* 2007; Del Hoyo and Collar 2014; Sigrist 2007 and 2012; Paglia *et al.* 2012; Piacentini *et al.* 2015; Iop *et al.* 2016; Segalla *et al.* 2016; Costa and Bérnils 2018). The carcasses were assessed and the number of occurrences per kilometers were documented. The conservation status of each species was retrieved from the ICMBIO (2018) and IUCN (2023) red lists. Our sample included wild and domestic animals, as well as unidentified species.

Carcass handling and data collection. Each carcass was evaluated to determine the time of exposure on the highway. The categories were (A) new roadkill (no rigor mortis, fresh blood, a dying specimen), (B) dead for 0–12 hours (beginning of or full rigor mortis, coagulated blood, no putrefaction and no odor), (C) dead for 12–36 hours (no rigor mortis, early putrefaction, odor, coprophagous Diptera or Coleoptera larvae), (D) dead for 36 hours–5 days (putrefaction, anatomically intact carcass), and (E) more than 5 days (decomposed carcass, no putrefaction or odor, Diptera or Coleoptera pupa) (Oates *et al.* 1984; Brooks 2016). Next, we documented (a) the time each animal was spotted, (b) the taxa and (c) the odometer reading. Photographs were taken before the disposal of each carcass. The collected data were organized in Microsoft Excel® 2017 worksheets.

Data analysis. The Spearman Correlation Coefficient (r), Kruskal-Wallis (H) and Chi-square (χ^2) tests were used to estimate the associations between the class and order levels of the taxa, in relation to seasonality and time of exposure, with 1,000 bootstrap repetitions. Statistical significance was set at $\alpha \leq 0.05$. The Mann-Whitney (U) test was used to measure the relationships between the above variables, the time of carcass exposure, or the habits of

the roadkill specimens. The time of the death was estimated by observing the degree of carcass decomposition. The Levene Test was used to assess the homogeneity of variance between the class and order levels of the taxa, seasonality and time of exposure (Castellan Jr. and Siegel 2006; Zar 2010; Härdle and Simar 2019). The relative abundance of each taxon was calculated using the species percentage in relation to the total number of animal road deaths, according to class and order. The frequency of occurrence was calculated as a percentage of the season in which the samples were documented in relation to their total number. The total scores for each category were extracted directly from the Excel spreadsheet using the data filter tool.

RESULTS

Additional File 1 presents data regarding animal deaths following vehicle collisions along the RS-040 highway, between August 2015 and March 2019. A total of 3,016 km and 104 trips were completed. The 2,371 dead animals were distributed into 137 species, and 29 orders. Our sample included wild ($n = 2,081$), domestic ($n = 217$), and unidentified ($n = 73$) animals. The data showed that an average of 0.78 animals were killed per km. The representativity per class (Figure 2) included mammals ($n = 1,223$; Figure 3), birds ($n = 704$; Figure 4), reptiles ($n = 406$), and amphibians ($n = 38$) (Figure 5).

Among domestic animals, there were mammals ($n = 208$) and birds ($n = 9$). The most frequent carcasses were those of white-eared opossums (*Didelphis albiventris*, $n = 559$) (Figure 3A) followed by black-and-white tegus (*Salvator merianae*, $n = 129$) (Figure 5A), and domestic cats (*Felis catus*, $n = 129$) (Additional File 1). Regarding coypus (*Myocastor coypus*) road deaths, 48 of the 102 carcasses were documented at the Capivari river and surroundings (Additional File 1). Among the dead birds, we counted 394 passerines, and some of the most affected ones were shiny cowbirds (*Molothrus bonariensis*, $n = 54$), red-crested cardinals (*Paroaria coronata*, $n = 50$) (Figure 4A), and chestnut-capped blackbirds (*Chrysomus ruficapillus*, $n = 41$) (Figure 4B). Fauna road mortality peaked in spring ($n = 812$, 34.2%) and summer ($n = 601$, 25.3%), and there were significant differences between seasons and roadkill classes ($\chi^2 = 129.6$; $p < 0.000$) (Figure 6), and seasons and exposure times ($\chi^2 = 75.2$; $p < 0.000$), respectively.

A total of 1,187 animal deaths were distributed into exposure-time categories A ($n = 550$), B ($n = 483$) and C ($n = 154$, a third part of that category) and were estimated to have occurred from the previous night until our arrival, relative to half of the daily monitoring periods. While 1,969 dead wild an-

imals were categorized as least concern specimens, we recorded 81 animals with some degree of threat. In addition to significant biodiversity, significant associations were drawn between classes, seasons, and exposure times in relation to the time of day ($U = 496,510.00$ - classes; $U = 542,769.5$ - seasons; $U = 526,913.5$ - exposure times; all considered $p < 0.000$). We documented 74 unidentified run over animal car-

riages, most of which ($n = 47$) were small and completely crushed, torn apart or decomposed.

DISCUSSION

Brazil is the largest South American country, with over 200 million inhabitants distributed across a ge-

ographical area of approximately 8.5 million km² (IBGE 2014b). Brazil is also one of the most biodiverse countries, with 148,000 animal species (Joly *et al.* 2019) including approximately 4,500 known terrestrial vertebrate species (Paglia *et al.* 2012; Piacentini *et al.* 2015; Costa and Bérnils 2018; Segalla *et al.* 2016). Biodiversity loss is one of the most dramatic environmental problems, illustrated by the 69% drop in worldwide wildlife populations since 1970 (WWF 2022). In Brazil, an alarming 15 wild animals are estimated to be killed per second by vehicle collisions, working out to around 475 million dead animals each year (CBEE 2022). Given this backdrop, and in order to assess the effects of roads on wildlife mortality and define mitigation measures, steps must first be taken to understand which species and how many specimens are killed by vehicle collisions (Gonçalves *et al.* 2018). We found that an average of 0.78 animals per km, or 0.22 animals per km per year were killed on the RS-040 highway (Additional File 1). This number was higher than the findings of other studies (Rosa and Mauhs 2004; Turci and Bernarde 2009; Cunha *et*

al. 2010; Silva *et al.* 2013; Ferreira *et al.* 2023). As shown in previous reports (Costa and Dias 2013; Grilo *et al.* 2018), there was a pattern of affected animal per class: mammals > birds > reptiles > amphibians. However, other authors have found a reversed predominance of classes, in which the number of passerine (Guinard *et al.* 2012), and amphibian (Ferreira *et al.* 2023) deaths were the highest. We speculate that these results may be influenced by biome-dependent biodiversity and natural species distribution in addition to others factors (Cáceres *et al.* 2010; Abra *et al.* 2021).

Mortality estimates may be affected by (a) the removal of carcasses between the time of death and scientific fieldwork, and (b) detectability because it is unlikely that all carcasses can be spotted and assessed, particularly when covering an area by car, once weekly (Slater 2002; Antworth *et al.* 2005; Prosser *et al.* 2008; Teixeira *et al.* 2013). Carcass permanence on roads can be influenced by weather, scavenger activity, and traffic flow (Slater 2002, Santos *et al.* 2016). Carcass size, roadside vegetation cover, survey

Figure 4. Bird roadkill along the RS-040 highway, 2015-2019. Juvenile red-crested cardinal (*Paroaria coronata*) (A), chestnut-capped blackbird (*Chrysomus ruficapillus*) (B), slaty-breasted wood-rail (*Aramides saracura*) (C), and juvenile roadside hawk (*Rupornis magirostris*) (D).

methods, and researcher training can also influence detectability (Hobday and Minstrell 2004, Santos *et al.* 2016). Although small carcasses remain for significantly less time on the road than larger ones (Teixeira *et al.* 2013), we managed to document around 400 carcasses weighing up to 50 g (Belton 2004), most of which were small birds that had died between dawn and the time of our documentation. Perhaps due to detection issues and removal rates associated with monitoring via car and once weekly fieldwork, our numbers for small vertebrates (amphibians, reptiles, and passerines) were probably too conservative (Teixeira *et al.* 2013; Santos *et al.* 2016). Amphibians (Ferreira *et al.* 2023) and the smallest wild bird order, Passeriformes (Guinard *et al.* 2012) have been reported as the most affected by vehicle collisions. While Ferreira *et al.* (2023) monitored the road via motorcycle, Guinard *et al.* (2012) also used a car. Additionally, animals that collide with vehicles may collapse in or move to places where they die undetected (Zaleski *et al.* 2009). Baker *et al.* (2004) estimated

that 31.48% of roadkill carcasses were found a distance away from the roads. Other animals, whether they are run over on purpose or not, are collected to be eaten by humans (Zaleski *et al.* 2009; Oliveira *et al.* 2023). Assessments of the coypu (*Myocastor coypus*) and armadillo (*Dasypus novemcinctus*) specimens in RS (Cruz *et al.* 2022) suggest there is local habit of consuming these animals. Therefore, the possibility of intentional collisions cannot be dismissed. The meat from roadkill may also pose health risks to humans (Oliveira *et al.* 2023). In addition, collisions with large mammals are also a threat to human safety and represent an economic cost to society (Abra *et al.* 2019). The worse documented accidents involved humans and two horses.

Although many carcasses may have been removed by scavengers before our arrival (Teixeira *et al.* 2013), we documented 1,187 road deaths that were thought to have happened from the night before ($n = 637$) to our arrival ($n = 550$). Opossums ($n = 559$) and domestic cats ($n = 129$) (Additional File 1) were

Figure 5. Reptiles and amphibian roadkill along the RS-040 highway, 2015-2019. Black-and-white tegu (*Salvator merianae*) (A), black-bellied slider (*Trachemys dorbigni*) (B), mussurana (*Boiruna maculata*) (C), and whistling frog (*Leptodactylus* sp.) (D).

the most affected mammals. Both have crepuscular and nocturnal habits (Paglia *et al.* 2012; Piccione *et al.* 2013). Other authors have reported similar findings (Mazerolle 2004; Zaleski *et al.* 2009; Pagany 2020). In addition, carnivores occupy large territories and often are forced to cross several highways, partly because of scavenging (Rosa and Mauhs 2004; Costa and Dias 2013; Ferreira *et al.* 2023). A total of 347 carnivores (Figure 2) were counted in our sample, including domestic cats and dogs. Among the 2,371 documented road deaths, the white-eared opossum (*Didelphis albiventris*), which may also feed on carrion (Ferreira *et al.* 2023), was the most affected species. White-eared opossum road fatalities represented 23.5% of all deaths, and were distributed over almost the entire stretch of highway. This is probably because it is a very common, opportunistic and widely distributed mammal in many regions of Brazil (Paglia *et al.* 2012), including anthropized urban areas (Rosa and Mauhs 2004). The same reasons may explain why these marsupials are the lead-

ing mammal to be surrendered at the wildlife triage center (*Centro de Triagem de Animais Silvestres – CETAS*) of the Brazilian environmental agency (*Instituto Brasileiro do Meio Ambiente e dos Recursos Naturais Renováveis – IBAMA*) in RS (Cruz *et al.* 2022). The desire to get rid of them (Cruz *et al.* 2022) may also have led some humans to intentionally run over some of these animals in disgust (Turci and Bernarde 2009; Ferreira *et al.* 2023). Domestic cats and dogs that range freely in natural areas are a conservation concern due to competition, predation, disease transmission or hybridization with wild animals (Ferreira *et al.* 2011; Szyrwelski *et al.* 2023). Domestic dogs ($n = 76$) and cats ($n = 129$) (Additional File 1), which are major anthropogenic causes of biodiversity loss (Mori *et al.* 2019), were among the most affected mammals. While this finding could illustrate the relative conservation effect of roads on some wild animal populations (Rytwinski and Fahrig 2013, Tatewaki and Koike 2018), their presence, abundance and spaces are heavily dependent on human

Figure 6. Distribution of fauna deaths from 2015–2019 (by class and season) along the RS-040 highway.

settlements (Ferreira *et al.* 2011).

Birds, particularly the granivorous species were the second largest affected group, probably because of their habit of foraging grains that fall from trucks, especially during harvest time in agricultural areas (Costa and Dias 2013). A total of 428 birds were killed during the rice harvest, from December to April (Additional File 1). Also, the seeds from grasses growing along the roadside in Rio Grande do Sul (Ferreira *et al.* 2008) are potential food sources for granivores (Polak *et al.* 2013). Seeds from *Brachiaria decumbens*, *Paspalum notatum*, and *Eragrostis plana* among other grass species fall to the asphalt (visually detected during fieldwork) where birds easily see them. Frequent granivorous bird deaths included

the shiny cowbirds (*Molothrus bonariensis*), red-crested cardinals (*Paroaria coronata*) (Figure 4A), and chestnut-capped blackbirds (*Chrysomus ruficapillus*) (Figure 4B; Additional File 1). The increase in their distribution ranges and populations (Cruz *et al.* 2021) coupled with deforestation (Morante-Filho *et al.* 2015) may also contribute to this tendency. However, these birds may actually benefit from road-adjacent foraging areas alongside roads, and a potentially positive effect of roads and anthropogenic structures on their populations (Morelli *et al.* 2014), even if some die as a result. Similar to other studies (Ferreira *et al.* 2023), we identified other granivorous birds in our sample, mostly Columbiformes ($n = 99$), such as eared-doves (*Zenaida auriculata*, $n = 66$) and ground-

doves (*Columbina picui* and *C. talpacoti*, $n = 30$). The risk factor linked to small animals' size was another finding in our sample, mostly associated with passerines. This was also reported previously (Guinard et al. 2012). Cuculiformes ($n = 67$) also deserve a mention here. These birds may have collided with vehicles when hunting for their usual sources of food, such as invertebrates, amphibians and small snakes that are easily seen on the asphalt. Moreover, the vegetation and fences along the roadside may serve as observation perches for predators. These birds, as well as raptors, were probably responsible for reducing the number of amphibian and reptile in our sample (Donázar et al. 1993; Meunier et al. 2000; Lambertucci et al. 2009). Scavengers have a high risk of colliding with vehicles (Taylor and Goldingay 2004, Kociolek et al. 2015). Assuming that the typical territory size for similar raptors is at least 40 hectares (Soares et al. 2008), it is reasonable to think that the 15 scavenger birds we documented (*Rupornis magnirostris*, *Caracara plancus*, *Coragyps atratus*, etc.) may indicate an increased prevalence of the category. This is because a straight line of 80 km could hypothetically cover about 20 territories. However, we may have lost some raptor samples, and their territories may not necessarily have similar dimensions along the highway.

While reptiles also scavenge, they are further attracted to the warmth of asphalt roads (Gonçalves et al. 2018). About 80% of all reptile road deaths in our sample occurred in the spring and summer, when the asphalt absorbs the greatest amount of solar radiation and reptiles exhibit the greatest level of activity (Bonnet et al. 1999). The black-and-white tegu (*Salvator merianae*, $n = 129$), and black-bellied slider (*Trachemys dorbigni*, $n = 73$) were the most affected reptile species in our study. A total of 178 snakes were documented, and the most frequent ($n = 47$) species was the Patagonia green racer (*Philodryas patagoniensis*), whose congener run-off-fieldsnake (*P. nattereri*) has also been the leading snake species in road deaths in northeast Brazil (Ferreira et al. 2023). Almost all the poisonous snakes we found ($n = 23$) were *Bothrops* sp., mostly ($n = 12$) Jararacas (*B. jararaca*). The higher prevalence of reptile roadkill has been attributed to their immobility during thermoregulation (Filius et al. 2020) and intentional vehicular collisions with animals considered dangerous or disgusting by humans (Turci and Bernarde 2009; Ferreira et al. 2023). Except for winter, when there was an increase in mammalian deaths (from 50% to 70%), and a decrease in reptile deaths (from 20% to 9%) in autumn-winter, there were no additional discrepancies regarding road deaths in other animal classes between seasons. The highest peak was in spring (34.24%) followed by summer (25.34%), au-

tumn (20.57%) and winter (19.85%) (Figure 6). Factors such as food scarcity and scavenging on roads may have influenced the winter data, mostly regarding medium-sized mammals (Fahrig and Rytwinski 2009; Rytwinski and Fahrig 2013). It was difficult to identify a seasonal pattern of variation for the birds in our study, perhaps due to their considerable diversity (75 species, 18 orders; Additional File 1) and the lower roadkill detection rate (Santos et al. 2012). While the number of road deaths usually increases during migration (Mazerolle 2004), and our study area is a migratory route (Bencke et al. 2010), we did not find any associations. The leading amphibian species in our sample were whistling frogs (*Leptodactylus* sp.) and floating frogs (*Pseudis* sp.), which are common in the environments we chose (Iop et al. 2016; Segalla et al. 2016).

Traffic significantly increases the risk of wildlife-vehicle collisions (Pagany 2020). The RS-040 highway is very busy, especially during the summer because it connects the capital to the nearest beaches (EGR 2023). This was why we expected higher numbers of roadkill than those we actually documented in the summer. Perhaps heavier traffic, increase in noise and car headlights made the animals avoiding the highway (Rosa and Mauhs 2004; Barthelmess and Brooks 2010; Weiss and Vianna 2012; Kioko et al. 2015). Stretches of road near or between forest fragments, or near bodies of water, are usually spaces of higher risk (Pagany 2020; Costa and Dias 2013). Almost half of the coypus (*Myocastor coypus*) road deaths were documented near the Capivari river (Figure 1, Additional File 1), suggesting that it is a critical conservation space and that the species could benefit from a wildlife crossing structure (Abra et al. 2021; Huijser et al. 2022). Most of the dead wild animals were categorized as least concern specimens, an expected result linked to their population size and distribution (Rytwinski and Fahrig 2012, 2013). However, the impacts of the decreasing abundance of these common species are a growing global conservation concern (Winfree et al. 2015; Baker et al. 2019). The loss of their ecosystem services could lead to greater repercussions than those of rare species (Winfree et al. 2015; Baker et al. 2019). The black-bellied slider (*Trachemys dorbigni*) was the second-largest group of reptiles in our sample and is considered a near threatened species in RS (ICMBIO 2018) that suffers the added effect of illegal trafficking (Cruz et al. 2022) as negative impacts to the species. Furthermore, the Northern Tiger Cat ($n = 3$) (*Leopardus tigrinus*) is considered a vulnerable species in RS (ICMBIO 2018). Speed reducers, proper signage and landscape management along roads and wildlife passages are all suitable mitigation measures against wildlife-vehicle collisions (Cunha et al. 2010; Silva et al. 2013; Huijser et

al. 2022; Huijser *et al.* 2022). Wildlife passages re-establish connectivity between environments (Abra *et al.* 2021), enhancing the movement of species, population survival, viability, and dispersion (Godwin and Fahrig 2002; Corlatti *et al.* 2009; Huijser *et al.* 2022). In Brazil and other countries, environmental education for drivers is another key point to combating the problem (Crawford and Andrews 2016; Ferreira *et al.* 2021). The massive expansion of roads projected globally by 2050, enough kilometers to encircle the planet more than 600 times, mostly in developing nations and in tropical and subtropical regions with high biodiversity and environmental values (Alamgir *et al.* 2017) coupled with the huge economic losses imposed on communities due to animal-vehicle collisions (Abra *et al.* 2019), highlight some of our alarming future challenges.

CONCLUSION

This inventory of wildlife roadkill showed a considerable biodiversity loss of local wild animals, mostly mammals and birds. However, it is plausible to think we may have underestimated the number of wildlife-vehicle collisions and deaths. While most of the animals belonged to the least concern species, 81 currently face some degree of conservation threat. Although threatened species must be considered a priority in conservation, we highlight the importance of maintaining the abundance of common species. We also documented a considerable number of domestic cats and dogs. The exact conservation effect of losing these predators is unknown, but there might be some benefit for their potential prey. In order to protect biological diversity, mitigation measures ought to be put in place to control the impacts of roads on local fauna, especially in critical spaces like the Capivari river and surroundings. Environmental education for drivers could raise awareness of this frustrating and severe loss. As vehicular collisions can cause animal suffering, ethical issues are also involved in these incidents.

ACKNOWLEDGMENT

We are grateful to CMPC Celulose Riograndense Ltda. for their financial support, and the Fundação de Apoio da Universidade Federal do Rio Grande do Sul for administrative support. We also are grateful to the anonymous reviewers for their helpful comments. This study is part of project no. 23644, which was approved by the university Animal Ethics Committee at UFRGS.

DATA AVAILABILITY

All data was included in the submission and additional file material.

CONFLICT OF INTEREST

The authors declare that they have no known competing financial interests or personal relationships that could have influenced the work reported in this paper.

CONTRIBUTION STATEMENT

GT, TP, VS, WN and CC wrote the original draft, organized and analyzed the data. TP, PW and WN carried out the fieldwork. PW and CC provided resources and supervision. GT, TP, VS, PW, WN and CC participated in the design of the study and presentation. All authors contributed to the article and approved the final version of the manuscript.
